

## List of Aerosol Generating Procedures

The below points are compiled from information available on the CDC website, [click here to access](#).

### Key Points

- Aerosol-generating procedures (AGPs) performed on patients are more likely to generate higher concentrations of infectious respiratory aerosols than coughing, sneezing, talking, or breathing.
- AGPs potentially put healthcare personnel and others at an increased risk for pathogen exposure and infection.
- Development of a comprehensive list of AGPs for healthcare settings has not been possible, due to limitations in available data on which procedures may generate potentially infectious aerosols and the challenges in determining if reported transmissions during AGPs are due to aerosols or other exposures.
- There is neither expert consensus nor sufficient supporting data, to create a definitive and comprehensive list of AGPs for healthcare settings.
- Commonly performed medical procedures that are often considered AGPs, or that create uncontrolled respiratory secretions, include:
  - open suctioning of airways
  - sputum induction
  - cardiopulmonary resuscitation
  - endotracheal intubation and extubation
  - non-invasive ventilation (e.g., BiPAP, CPAP)
  - bronchoscopy
  - manual ventilation

Based on limited available data, it is uncertain whether aerosols generated from some procedures may be infectious, such as:

- nebulizer administration\*
- high flow O<sub>2</sub> delivery

\*Aerosols generated by nebulizers are derived from medication in the nebulizer. It is uncertain whether potential associations between performing this common procedure and increased risk of infection might be due to aerosols generated by the procedure or due to increased contact between those administering the nebulized medication and infected patients.
